

# Azure Logic Apps

## Workflow Automation and Integration

### 1. What are Azure Logic Apps?

Azure Logic Apps is a cloud service in Microsoft Azure used to create automated workflows that integrate applications, services, systems, and data. Logic Apps provide a visual workflow designer and a large collection of connectors for communicating with external and Azure services.

### 2. Workflows

A Logic App workflow consists of a trigger followed by one or more actions. The trigger starts the workflow when an event occurs. Actions perform operations such as calling an API, sending an email, reading a database record, transforming data, or sending a message to a queue.

### 3. Triggers

Logic Apps support many trigger types. A workflow can start when an HTTP request is received, when a scheduled time is reached, when a message arrives, when a file is created, or when another connected service produces an event.

### 4. Connectors

Connectors allow Logic Apps to communicate with other applications and services. Microsoft provides connectors for services such as Azure Service Bus, Blob Storage, SQL Server, Microsoft 365, SharePoint, Salesforce, and many other systems. Connectors simplify integration by providing predefined operations.

### 5. Azure Logic Apps Standard and Consumption

Azure Logic Apps provides Standard and Consumption hosting options. Consumption workflows are commonly used for individual workflows that use a multitenant model. Standard supports workflows using a single-tenant model and provides additional capabilities for hosting and managing workflows. The appropriate option depends on workload, integration, networking, and operational requirements.

### 6. Common Use Cases

Logic Apps are commonly used for enterprise integration, business process automation, file processing, API orchestration, notification workflows, data movement, message processing, and connecting cloud services with on-premises systems.

### 7. Logic Apps and Azure Functions

Logic Apps and Azure Functions can be used together. Logic Apps are well suited to workflow orchestration and service integration, while Azure Functions are suited to executing custom code in response to events. A Logic App can call an Azure Function when custom processing or specialized business logic is required.
